A STEREOCHEMICALLY-CONSTRAINED ENKEPHALIN ANALOG

a-Aminoisobutyryl’ methionine§ enkephalinamide

1. Introduction

The discovery that the pentapeptides Tyr–Gly–Gly–Phe–Met (Met’-enkephalin) and Tyr–Gly–Gly–Phe–Leu(Leu§-enkephalin), present in the mammalian central nervous system [1,2], possess opioid activity has stimulated considerable interest in their conformations [3–15]. The enkephalins have been shown to bind to the opiate receptor in brain and displace naloxone, a powerful opiate antagonist [16]. The structures of the enkephalins have been the subject of a number of spectroscopic and theoretical investigations. There have been attempts to build a structural model for the pentapeptides that mimics the essential features of the morphine molecule [8–11]. From these studies conflicting suggestions have emerged about the low energy conformation of enkephalins and also the possible conformation of the pentapeptides at the opiate receptor site. A single crystal X-ray diffraction study of [Leu’] enkephalin has been reported [17], in which the molecule has been shown to possess a Gly²–Gly³ β-turn stabilised by two intramolecular hydrogen bonds between the CO and NH groups of Tyr¹ and the NH and CO groups of Phe⁴. This conformation has not been suggested by any of the spectroscopic or theoretical studies, though it was put forward earlier on the basis of empirical predictive procedures [9]. The presence of two glycine residues in enkephalin is likely to result in enhanced flexibility of the peptide backbone in solution. Consequently nuclear magnetic resonance (NMR) investigations may be confronted with the problem of dynamic averaging, between conformers of similar energies. The substitution of the Cα hydrogen atoms with alkyl residues in peptides, restricts conformational freedom. Experimental [18–20] and theoretical [21–23] studies have shown that the dimethyl analog of glycine, H₂N–(CH₃)₂–COOH, (α-aminoisobutyric acid, Aib) is an extremely sterically hindered amino acid capable of occupying only a small region of conformational space (φ –± 60°, ψ –± 30°) in the right- or left-handed 3₁₀ or α-helical regions of the conformational map [24]. Substitution of the glycine residues in enkephalin with a-aminoisobutyric acid residues should then lead to analogs with fewer conformational possibilities. We describe here the synthesis of the stereochemically-constrained enkephalin analog, [Aib² Met⁶] enkephalinamide (I).

2. Experimental

Amino acid methyl esters were prepared by the thionyl chloride–methanol procedure [25] while t-butyloxy carbonyl (Boc) amino acids were prepared as in [26]. The coupling reactions were carried out using dicyclohexylcarbodiimide (DCC). Removal of the Boc protecting groups were effected using HCl/tetrahydrofuran. The synthetic scheme is outlined in fig.1. [Aib² Met⁶] enkephalinamide was obtained as a white solid, thin-layer chromatography on Silica gel, Rₕ = 0.57 (n-butanol–acetic acid–water, 4:1:1). A faint ninhydrin negative spot at
$R_F = 0.83$ was also noted. Ultraviolet (methanol) $\lambda_{\text{max}} = 276$ nm. On addition of NaOH $\lambda_{\text{max}}$ was shifted to 296 nm (tyrosine absorption). Satisfactory 270 MHz $^1$H NMR spectra, in accordance with the structure were obtained on a Bruker WH-270 Fourier Transform NMR Spectrometer, at the Bangalore NMR Facility.

3. Results and discussion

The 270 MHz $^1$H NMR spectrum of I in (CD$_3$)$_2$SO is shown in Fig.2. The assignments of the resonances are indicated. It is interesting to note that the C$_{\alpha}$H$_2$ protons of Gly$^3$ are non-equivalent and appear as the AB part of an ABX spectrum centred at $-3.66$. The two methyl groups of Aib$^2$ are also non-equivalent as evidenced by the resonances at 1.38 and 1.406. Earlier studies have shown that the C$_{\alpha}$H$_2$ protons of both Gly$^2$ and Gly$^3$ in Met$^3$-enkephalin are non-equivalent in H$_2$O and (CD$_3$)$_2$SO, suggesting that the molecules are inflexible on a chemical shift timescale. Non-equivalence of the C$_{\alpha}$H$_2$ protons of Gly residues has also been used to support the view that ordered conformations exist in solution, for a tetrapeptide fragment of tropoelastin Boc–Val–Pro–Gly–Gly–OMe [27]. While geminal nonequivalence of the C$_{\alpha}$H$_2$ protons of Gly$^3$ and the CH$_3$ groups of Aib$^2$, is not conclusive evidence for the presence of ordered structures, it is likely that I adopts fairly well defined conformations in solution.

Preliminary studies indicate that I possesses high analgesic activity in rats, suggesting that the conformations necessary for receptor binding are still accessible in the Aib$^2$ analog. D-Ala$^2$-enkephalinamide [28,29] is a potent long lasting analgesic with a high affinity for the opiate receptor whereas the L-Ala analog exhibits only weak receptor binding. These results suggest that the conformations permissible for the D-Ala and Aib residues fit the opiate receptor whereas the conformations adopted by the L-Ala residue are unfavourable for receptor interactions. Theoretical studies [30] have shown that peptide sequences with alternating configurations (DL or LD) have a high probability of forming $\beta$-turns [31]. $\alpha$-Aminoisobutyric acid residues have also been shown to have a very strong tendency to initiate the formation of $\beta$-turns, from X-ray diffraction and spectroscopic investigations of Aib-containing peptides [18–20]. It is significant that the solid state conformation of Leu$^5$-enkephalin possesses a $\beta$-turn with Gly$^2$ and Gly$^3$ as the central residues [17]. A conformation that is accessible to all three active enkephalin analogs involves the $\beta$-turn with residues 2 and 3 at the corners. It is likely that binding to the
opiate receptor can then be accomplished by reorientation of the Tyr and Phe sidechains.

The torsional angles allowed for residue 2 as judged by the activity of the D-Ala² and Aib² analogs is restricted to the region $\phi \sim -60^\circ$ and $\psi \sim 30^\circ$, since the Aib residue is energetically confined largely to the regions $\phi \sim \pm 60^\circ$ and $\psi \sim \pm 30^\circ$. It is noteworthy that the values obtained in the X-ray study [17] for Gly² are $\phi = 59^\circ$ and $\psi = 25^\circ$. Based on computer modelling studies the D-Ala residue in D-Ala²-enkephalinamide has been suggested to have $\phi = 160^\circ$ and $\psi = -87^\circ$ in the conformation involved in receptor binding [32]. These values of $\phi$ and $\psi$ would lead to a very high energy for the Aib² analog, which is unlikely to be offset by binding interactions at the opiate receptor. The backbone conformation at the receptor site is therefore unlikely to involve large departures from the $\beta$-turn involving residues 3 and 3. The judicious use of $\alpha$-alkyl amino acid residues in preparing synthetic analogs may allow a better definition of the biologically active conformation. Further studies on the synthesis of the Aib² and [Aib² Aib³] enkephalin analogs and studies of their conformations and biological activity are in progress.

Acknowledgements

We thank Dr J. Lakshmanan for testing the biological activity of the enkephalin analog. Financial support from the UGC is gratefully acknowledged. R.N. is the recipient of a fellowship from the Department of Atomic Energy. Contribution no. 117 from the Molecular Biophysics Unit, Indian Institute of Science, Bangalore, India.
